

ADVANCED POWER SYSTEM ANALYSIS & DESIGN

Introduction

The degree of development of sources of energy to accomplish useful work is one of the measures of industrial progress. The discovery of sources of energy in nature, the transportation of energy in its various forms from one place to another, and the conversion of energy to a more serviceable form are essential parts of an industrial economy. An electric power system is one of the tools of converting and transporting energy.

The only means of transporting energy in the form of electricity is over transmission lines. Gas is transported by pipelines. Railroads, ships, and pipelines carry oil over long distances. Coal is shipped long distances by rail and water. When coal is the primary source of electric energy, the electric transmission line becomes a competitor of railroads and ships in transporting energy. The choice of location of a steam generating station near a coal mine or near a load center, provided there is a good water supply at both places, may depend upon the difference in cost of transmitting electric energy and transporting coal from the mine to the load. Pipelines are increasing rapidly and are becoming a major competitor of the electric transmission line by providing low-cost transportation of energy.

Hydroelectric power is inexpensive only if the cost of its transmission is low. The economy of transporting energy in one form instead of another is influenced by whether the demand for the energy is continuous or intermittent, by the distance involved, and by the cost and practicability of storage facilities. The determining factor is the final cost, including transportation charges, of the energy in the desired form.
