methods have evolved with the capability to measure CR time quantitatively one of which is Polarisation Spectroscopy Imaging PSI PSI measures the Red Blood Cell RBC concentration in tissue e.g. the skin and can be used to measure CR time

Objectives The purpose of this study was to establish basic characteristics for quantified CR qCR identify possible influencing factors in healthy subjects and to investigate how this relates to current practice We also sought to identify technical demands for transfer of the technique into clinical studies In paper I we analysed the qCR time characteristics at 5 different skin sites forehead sternum volar forearm finger pulp and dorsum finger The objective of paper II was to investigate the inter and intra observer variability of naked eye CR assessments of different professions nurses doctors and secretaries representing laymen In paper III we observed the effect of low ambient temperature on the qCR time in different skin sites In paper IV we transferred the equipment from a laboratory to a clinical setting in the Emergency Department ED for application on potentially critically ill patients In this study we evaluated the most important factors determining a reliable data collection and influencing the amount of data possible to analyse

Methods qCR time was measured in a total of 38 volunteers and 10 patients in different skin sites 25 skin sites at different ambient temperatures PSI TiVi 600 and 700 WheelsBridge AB Linköping Sweden was used to determine the rapid temporal changes in RBC concentration in skin during the CR manoeuvre

Films using a range of the first measurements from paper I were shown for assessment to 48 observers working in the ED

Results In paper I we could delineate qCR curves and suggest 2 possible equivalents to the naked eye observed CR time which we named Time to Return to Baseline 1 tRtB1 and Time to Peak tPk We demonstrated differences in qCR curves depending on skin site and possibly due to skin temperature In paper II we showed a poor inter and intra observer reproducibility in visually estimating the CR time regardless of profession clinicians or laymen Paper III demonstrated a rapid effect of ambient temperature on qCR time in peripheral skin sites such as finger pulp The forehead regarded as a more central skin site was the most temperature stable site and showed least variability in qCR time as determined using tRtB1 Paper IV a study on patients in an ED setting yielded assayable data in 80% of the measurements We identified critical performance parameters to address in the further development of a more robust easy to use device for future validation of the possible relevance of qCR in patient triage and monitoring

Conclusions CR time can be quantified using PSI Quantified CR time demonstrated a large variability between different skin sites specifically skin temperature was shown to be an important factor influencing qCR time particularly at the fingertip Naked eye estimates of CR time were highly variable both within and between observers Agreement between quantified CR time and naked eye estimates was poor The prototypic PSI technique was feasible in a clinical setting and with further improvements clinical evaluation of qCR in relation to relevant patient outcomes will be possible
