Dynamic Response of Containment Vessels to Blast Loading ,1982 The dynamic response of steel spherical containment vessels loaded by internal explosive blast was studied by experiments computations and analysis Instrumentation used in the experiments consisted of strain and pressure gauges and a velocity interferometer Data were used to rank the blast wave mitigating properties of several filler materials and to develop a scaling law relating strain filler material and explosive energy or explosive mass

Containment Atmosphere Response to External Sprays ,1995 The application of external sprays to a containment steel shell can be an effective energy removal method and has been proposed in the passive AP 600 design Reduction of the steel shell temperature in contact with the containment atmosphere enhances both heat and mass transfer driving forces Large scale experimental data in this area is scarce therefore the measurements obtained from the E series tests conducted at the German HDR facility deserve special

attention These long term tests simulated various severe accident conditions including external spraying of the hemispherical steel shell This investigation focuses upon the integral response of the HDR containment atmosphere during spray periods and upon methods by which lumped parameter system codes like CONTAIN model the underlying condensation phenomena Increases in spray water flowrates above a minimum value were ineffective at improving containment pressure reduction since the limiting resistance for energy transfer lies in the noncondensable vapor boundary layer at the inner condensing surface The spray created an unstable condition by cooling the upper layers of a heated atmosphere and thus inducing global natural circulation flows in the facility and subsequently abrupt changes in lighter than air noncondensable J2 He concentrations Modeling results using the CONTAIN code are outlined and code limitations are delineated A Design Guide and Specification for Small Explosive Containment Structures, 1994 The design of structural containments for testing small explosive devices requires the designer to consider the various aspects of the explosive loading i e shock and gas or quasistatic pressure Additionally if the explosive charge has the potential of producing damaging fragments provisions must be made to arrest the fragments This may require that the explosive be packed in a fragment attenuating material which also will affect the loads predicted for containment response Material also may be added just to attenuate shock in the absence of fragments Three charge weights are used in the design The actual charge is used to determine a design fragment Blast loads are determined for a open_quotes design charge close_quotes defined as 125% of the operational charge in the explosive device No yielding is permitted at the design charge weight Blast loads are also determined for an over charge defined as 200% of the operational charge in the explosive device Yielding but no failure is permitted at this over charge This guide emphasizes the calculation of loads and fragments for which the containment must be designed The designer has the option of using simplified or complex design analysis methods Examples in the guide use readily available single degree of freedom sdof methods plus static methods for equivalent dynamic loads These are the common methods for blast resistant design Some discussion of more complex methods is included Generally the designer who chooses more complex methods must be fully knowledgeable in their use and limitations Finally newly fabricated containments initially must be proof tested to 125% of the operational load and then inspected at regular intervals This specification provides guidance for design proof testing and inspection of small explosive containment structures *An Optimized Configuration of an Enclosure Structure for Safe Containment of Internal Blasts* Aaron D. Gupta, Henry L. Wisniewski, ARMY BALLISTIC RESEARCH LAB ABERDEEN PROVING GROUND MD., 1981 Large deflection elastic plastic response of a hemispherical containment shell configuration clamped to a horizontal rigid foundation and subjected to an internal blast was analyzed using a finite difference structural response code PETROS 3 5 The reflected overpressure peak was estimated from a scaled distance of the wall from the point of detonation based on a conservative cube root scaling law and an exponential decay given by the modified Friedlander equation The residual quasi static overpressure was obtained from an equation developed by Kinney and Sewell based on the

ratio of the available vent area and the internal volume. The results indicated the initiation of flexural waves at the boundary propagating towards the pole and converging thereby altering the spherically symmetric breathing mode of response of the centrally loaded hemisphere. The peak deflection predicted by the code occurred at the pole and permanent deflection was found to be quite small after releasing the load. Transient strain components at the inner and outer surfaces near the clamped edge due to largely elastic oscillations showed the effect of bending deformation superposed on the membrane components. In conclusion, the protective structure was found to be efficient and cost effective and capable of blast containment with an adequate margin of safety.
