

The Human Genome Project

whose signature goal was to generate the first sequence of the human genome.

It is the collection of all the genetic information of a cell including coding non-coding and regulatory elements.

It started in 1990 and completed in 2003. HGP produced a genome sequence that accounted for over 90% of the human genome. It was as close to complete as the technologies for sequencing DNA allowed at the time.

Techniques used in HGP:

DNA extraction → restriction digestion to cleave DNA into thousands of fragments → fragments are inserted into the λAC - bacterial artificial chromosomes → PCR to amplify fragments → a library of fragments was constructed → sequencing → base sequence overlapping to string sequenced pieces together.

Cook et al. HGP

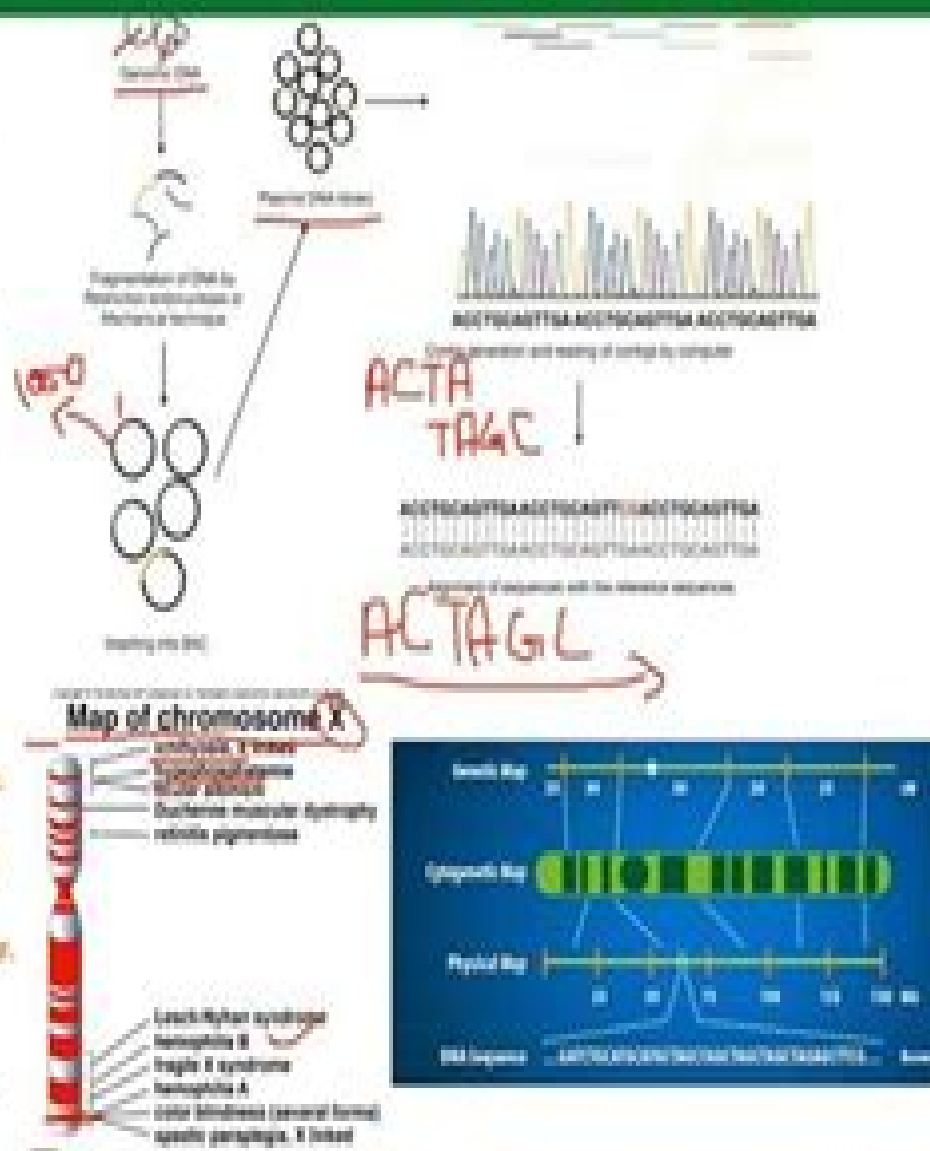

1. to construct a genetic map of the human genome

To find out how genes are arranged along the length of each chromosome. This helps in identifying disease causing genes. E.g. Huntington disease have unique sites where restriction enzymes cut DNA. The test for HD relies on this difference from the normal.

Human genome is 33 times larger than any other genome sequenced so far

2. To construct a base sequence map.

There are 3 billion base pairs in human genome. Knowing the base sequence of normal genes will help in treatment of certain human genetic diseases.
